Took's Court, Chancery Lane, London.

TO

THE RIGHT HONOURABLE

LORD SOMERVILLE.

My LORD,

Many of the greatest and best men, in every age, have paid attention to Agriculture. The Husbandmen of the present day, can bear ample and grateful testimony to the national benefits derived from your Lordship's personal exertions in promoting Agricultural Science. Every thing that could have been hoped, from ample munificence and most liberal encouragement,—from profound theory, and enlightened practice,—calling the attention of the United Kingdom to improved modes of cultivating the soil, and managing cattle, has already been accomplished by Lord Somerville, to a degree once rather to be wished for, than seriously expected.

Your Lordship's patronage has put the public in possession of a prodigious fund of useful knowledge, the result of private experiment.

No department of your Lordship's favourite pursuit seems too humble for your Lordship's notice, if it shall conduce to general utility ; and, therefore, I presume to place the following Work under your Lordship's powerful protection ; impressed with the deepest sensations of gratitude for the honor done me, by indulging me with the permission to dedicate it to your Lordship.

I am, my Lord,

Your Lordship's

Most devoted

And most faithful humble Servant,

LAYTON COOKE.

33, Haymarket, February 24, 1813.

PREFACE.

HAVING frequently experienced, in the course of my agricultural pursuits, the want of a work like the present, it is natural to suppose that many others may sometimes have felt a similar inconvenience. Impressed with this idea, I have been induced to give publicity to the following Tables, which were originally intended only for my private reference.

The first, second, and third, were calculated with a view to lessen the expences attending the cultivation of the soil, and to improve the condition of the servants in husbandry by reducing several agricultural operations to fixed principles, thereby enabling the labourer to execute his work by measure instead of by the day.

I have omitted no opportunity of acquiring the necessary information to enable me to compose the Tables, shewing the net profitable weight of animals. The live and dead weights of those exhibited at Christmas Spring meetings in London, which are very properly made public, have, in part, furnished me with data to calculate the proportion, that the carcases of animals, in a perfectly ripe state, bear to the gross live weight.

To William Mellish, Esq. I am much indebted, for the very handsome manner in which he permitted me to ascertain the necessary particulars of the animals slaughtered at his yard. I also feel myself considerably obliged to Wm. Bowring, Esq. of the Victualling-yard, at Deptford, for the ready assistance he afforded me, and for the information he communicated.

To numerous other individuals I beg to tender my acknowledgements, for their kind attention, and the ingenuous manner in which they favoured me with the results of various experiments relating to this subject.

I dare not flatter myself that I have explained the Tables in such a manner as will meet with the approbation of every person who may do me the honor to consult them. To some, the Explanations may appear to require farther illustration and detail; while others may consider them to be treated in a style of unnecessary prolixity. It has been my study to avoid both extremes; but without forgetting, that, in a Work like the present, unnecessary prolixity is a fault of much less moment, than to leave any matter of importance insufficiently explained to readers of common capacity and information.

Machines upon a simple construction, for weighing cattle alive, and Agricultural Implements on the most approved principles, forwarded by the Author to any part of the kingdom.

EXPLANATION

OF THE

TABLES.

INTRODUCTION.

It is observable, that, amidst the general zeal for agricultural improvement, to which some of the most distinguished characters in this country have condescended to turn their attention, the knowledge of the operative department, so essentially necessary to a profitable practice of the science, should have been almost wholly neglected.

The nature of the subject admitting very few opportunities of indulging the warmth of fancy, or colouring of imagination ; the characteristics of many works on agricultural subjects may, in some measure, account for its having been so little attended to : but the principal cause of the slow progress that has been made in this branch of rural science, may perhaps be attributed to the

aversion that many practical farmers have to commit the result of their experience to paper, particularly when calculations are indispensable for the illustration of their ideas.

The art of acquiring the greatest proportion of labour, more especially of manual labour, at the least expense, has by no means met with the attention it merits; neither has the comparative quantity of work, that ought to be performed with implements of different kinds, in fields of various sizes, ever been attempted to be ascertained with any degree of accuracy.

That the expenses attending the cultivation of the soil are enormous, and that the public burthen bears heavily upon the landed interest, will be granted by the majority of persons conversant with the subject: but that the most effectual plan to reduce the expenses of the farmer, would be to allow the labourers to earn greater wages than they do at present, is an hypothesis that probably may not at first be so readily admitted, though upon reflection, it will be found indisputably correct.

Self-interest is the predominant principle that influences human action. It consequently follows, that the greatest proportion of manual labour will be obtained, wherever the wages in-

crease in the same proportion as the labour. But every circumstance that tends to degrade or depress the spirit of the labourer, will likewise tend to weaken his ability, and lessen his inclination for useful exertion.

The change of character in the peasantry (a source of frequent complaint and universal regret) is, doubtless, attributable to the diminution of their domestic comforts. It would be idle to expect a miserable care-worn being to go to his daily employment with the same energy that he would do, had he an opportunity, by any extra exertion or attention, to procure the necessities of life for his family, and a sufficiency of wholesome nourishment to enable him to undergo the fatigue of his laborious occupation :—suitable encouragement should be afforded to the industrious ; which would be the likeliest mode of reclaiming the dissolute. If the same privileges be allowed to the latter which are enjoyed by the former, there will be but little hope of any amendment in the conduct of those who are idly inclined. And if it be considered, that, in four-fifths of South Britain, the daily wages of the labourers in husbandry are not more than barely sufficient to enable them to prolong a miserable existence, it will cease to be a matter of surprise,

that they should be supine in their manner, or appear indifferent to the interests of their employers: neither will it require more than a common share of sagacity to discover, that the effect produced by the sufferings of the labourer must ultimately prove inimical to the interest of the agriculturist; for the total incapacity of the former to perform a proper quota of work, must be the inevitable consequence of his inability to procure an adequate proportion of food and other necessaries to support him in a state of useful vigour, and relieve his mind from the misery occasioned by the sufferings of a wretched family.

In order to alleviate the distresses of the labouring class, and lessen their own expenses, agriculturists are most strenuously recommended to allow their men, as far as it is practicable, to execute all their work by MEASURE:—they will find, if the labourers earn four or five shillings a day by the piece, it will be cheaper than compelling them to work by the day at two shillings. There are very few operations that might not be executed by measure, though there has hitherto been no regular mode of ascertaining the value of manual labour attending those in which the aid of horses or oxen is necessary, as

plowing, harrowing, rolling, drilling, &c. The following Tables were calculated with the idea of simplifying those operations, and to render them applicable to fixed rules.

EXPLANATION OF TABLE I.

TABLE I. shews the space, in miles and decimal parts of a mile, over which any implement or machine, from 8 inches to 20 feet wide, requires to pass in plowing, harrowing, rolling, or otherwise working an acre of land, in fields of various dimensions. In the first column may be found the different widths of the implements, from 8 inches to 20 feet. The second column shews the space over which implements of each different width would respectively require to be moved, if the field were large enough to admit of an acre being worked without turning the implement. The third column shews the space over which the implement must be moved, if the field admit of furrows only half a chain long. The fourth column shews how far each implement must be moved, when the field admits of furrows $1\frac{1}{2}$ chain in length ; and so on to 20 chains.

It is estimated, that each implement is moved statute poles at every turn, or lands-end ; therefore, the smaller the field, the greater the space

over which an implement requires to be moved in working an acre.

EXAMPLE.

Question.—How many miles must the plough be moved, to plow an acre with furrows 9 inches wide, in a field admitting them to be 10 chains long?

Solution.—Parallel to 9 inches wide, and under 10 chains long, will be found 11.816: meaning 11 miles and .816 thousandth parts of a mile, which is the distance that it would be required to be moved to plow an acre with furrows of those dimensions.

To facilitate the calculation by decimals, the following Tables are subjoined :

Table VI. shewing the decimal corresponding to every pole in the mile.

Table VII. shewing the decimal corresponding to every pole in the acre.

Table VIII. shewing the decimal corresponding to every farthing in the shilling, or $\frac{1}{4}$ inch in the foot.

Table IX. shewing the decimal corresponding to every farthing in the pound.

Table X. shewing the decimal corresponding to every day in the year.

Table XI. shewing the decimal corresponding to every pound in the stone of 8 lb.

Table XII. shewing the decimal corresponding to every pound in the stone of 14 lb.

Table XIII. shewing the decimal corresponding to every pound in the score, or 20 lb.

Table XIV. shewing the decimal corresponding to every pound in the stone, trone weight.

By Table VII. the nearest number to .816 (see the above example) is .815, the decimal corresponding to 6f. 21p.; therefore 11.816 is equal to 11M. 6f. 21p.

Question.—If 3 harrows be 12 feet wide; what distance must they be moved to harrow an acre in a field, admitting of their being drawn 8 chains before they turn?

Solution.—In the column under 8 chains, and parallel to 12 feet wide, will be found .749—By Table VI. .749 is the decimal corresponding to 6 furlongs.

If the proper number of horses or oxen be applied to each implement, so that they may all be worked with equal ease to the animals drawing them; the proportionate number of acres that ought to be worked by each implement, may be found as follows:

EXAMPLE.

Required the number of acres a person with an implement 5 feet 6 inches wide, ought to work in a field admitting of furrows 9 chains long,—while another plows an acre with furrows 8 inches wide, in a field that admits of their being only 7 chains long.—By Table I. the number of miles the plough must be moved to plow an acre with furrows 8 inches wide and 7 chains long, is 13·691, and the space over which the implement 5 feet 6 inches wide requires to be moved in a field admitting of furrows 9 chains long, is 1·615 mile :—then, as the latter number is to one acre, so is the former number to the answer in acres.—

Mile.	Acre.	Miles.	Acres.
-------	-------	--------	--------

Or, as 1·615 : 1 :: 13·691 : 8·471.

By Table VII. the nearest number to ·471 is ·468; the decimal corresponding to 1R. 35P.: therefore 8·471 = 8A. 1R. 35P.

Should the number of acres that ought to be worked with an implement, in travelling a given number of miles, be required; divide the given number of miles by the distance in miles that the implement is required to be moved to work one acre: and the quotient will be the answer in acres.

EXAMPLE.

Suppose one horse, or more, travel 14 miles with an implement 6 feet 6 inches wide, in a field admitting the length of furrows to be 16 chains :—By Table I. it will work an acre, by moving $1\cdot361$ miles : then, as $1\cdot361 : 1 :: 14 : 10\cdot286 = 10. 1. 6.$
(see Table VII.)

EXPLANATION OF TABLE II.

THE value of the manual labour in working an acre with implements of different widths, in fields of various sizes, may be found by Table II. which is given in shillings and decimal parts of a shilling, and is calculated upon the supposition that the pay of a man attending upon his horses in the usual manner, and travelling 12 miles with a plough, or any other implement, is equal to the wages of a day-labourer ; and that he will be entitled to receive in a like proportion for the distance he may go with the implement beyond 12 miles.

It is to be observed, that the Table is calculated at one shilling *per day* : so if two shillings be the usual pay of a labourer, the sum found by the Table must be multiplied by 2 for the sum required :— and if two shillings and sixpence be the usual pay

of a labourer, the sum found by the Table must be multiplied by 2.5 ;—.5 being the decimal part of a shilling corresponding to 6d. (*see Table VIII.*) If three shillings be the usual pay of a labourer, the sum must be multiplied by 3 ; and so on for any other price *per day*.

EXAMPLE.

Required the expence of the manual labour of plowing a field of 12 acres in furrows 9 inches wide, admitting that, upon an average, the furrows might be 14 chains long ;—the usual pay of a daily labourer being two shilling ?

By Table II. parallel to 9 inches, and under 14 chains, is .9650 ; which being multiplied by 2, gives 1.930, the price of the manual labour of plowing an acre ; multiplied by 12, the contents of the field will produce 23.160 the answer.—By Table VIII. the nearest number to .160 is .166, the decimal corresponding to two-pence : therefore $23.160 = 1l. 3s. 2d.$

Again ; what ought be paid for the manual labour of plowing a field containing 10 acres, in furrows $8\frac{1}{2}$ inches wide, admitting them to be 16 chains long ;—the price of a daily labourer being two shillings and sixpence ?

By Table II. parallel with $8\frac{1}{2}$, and under 16

chains will be found 1.0153; which, multiplied by 2.5, is equal to 2.5372, the expense of the manual labour of plowing 1 acre, multiplied by 10 (the number of acres in the field) will produce 25.372 = 1*l.* 5*s.* 4 *$\frac{1}{2}$ d.*; the answer.

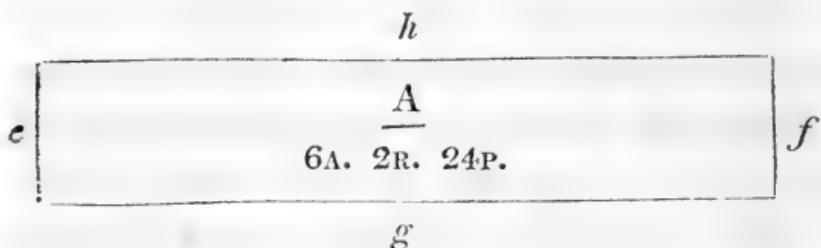

It is not recommended, that the horses should be suffered to remain longer than the usual time in the field:—but it is expected, that better use will be made of the time than is sometimes the case, when working by the day;—which, it is presumed, would make a difference of at least two days in ten: thus, in the above instance, the plowman would receive 1*l.* 5*s.* 4 *$\frac{1}{2}$ d.* for eight instead of ten days, and the farmer would have one fifth more work done by his horses.

Plowing by the acre is not a new idea; it has been partially practised many years in a county particularly distinguished for liberal and enlightened agriculturists.

It is a prevailing idea, that an acre is a proper day's work for a man with a plough: the size of the field, or the width of the furrow, is seldom taken into the account: notwithstanding, it is evident, (*see Table I.*) that a plough requires to be moved more than double the distance, in plowing an acre with furrows 8 inches wide, in a corner or narrow part of a field admitting of their being only 1 *$\frac{1}{2}$*

chain long, that it would be required to be moved to plow an acre with furrows 12 inches wide and 9 chains long.

Occupiers of the soil would do well to lay the arable part of their farms into large square fields. Small or narrow fields add considerably to the expense of cultivation; as may be seen by the following example :

Suppose the above diagram to represent field A, containing 6A. 2R. 24P. being 19 chains from the hedge e to the hedge f, and $3\frac{1}{2}$ chains from the hedge g to the hedge h; the width from each hedge to the inner side of each headland being 50 links; if double the width of the headland be deducted from the length of the side of the field, the remainder will be the length of the furrow: then, if one chain be deducted for the two headlands, the length of furrow from e to f would be 18 chains. To plow an acre in furrows 8 inches wide and 18 chains long (*see Table I.*) the plough requires to be moved 12.881 miles: multiplied by 6.65 (.65 being the decimal corresponding to

2R. 24P.—*see Table VII.*) will produce 85·658, the space in miles and decimal parts, over which the plough would be required to pass to plow field A from *e* to *f*. The expense of the manual labour in plowing an acre in furrows of the above dimensions, viz. 18 feet by 8 inches, at the rate of two shillings and sixpence per day, may be found as follows. By Table II. the expense at one shilling *per day* is 1·0734, multiplied by 2·5 produces 2·6835, the expense of the manual labour in plowing one acre; which being multiplied by 6·65, the contents of the field equal 17·845; which is the expense of the manual labour in plowing field A from *e* to *f*.

Should the same field be required to be plowed from *g* to *h*, in furrows 8 inches wide, deduct one chain for headlands, &c. and the furrows will be only $2\frac{1}{2}$ chains in length. By Table I. the number of miles the plough must be moved to plow an acre in furrows $2\frac{1}{2}$ chains long and 8 inches wide, is 16·077: multiplied by 6·65 (the contents of the field) equal 104·500 miles; and by Table II. the value of the manual labour at one shilling *per day* would be 1·3397 multiplied by 2·5 equal 3·349, the value of the manual labour in plowing one acre, multiplied by 6·65

equal 22·238 the value of the manual labour in plowing field A from *g* to *h*.

RECAPITULATION.

To plow field A from <i>g</i> to <i>h</i> in furrows 8 inches wide, the plough requires to be moved	miles. 10·4500	Expence of ma- nual labour in plowing field A from <i>g</i> to <i>h</i>	s. 22·238
To plow field A from <i>e</i> to <i>f</i> in furrows 8 inches wide, the plough requires to be moved.....	85·658	Expence of ma- nual labour in plowing field A from <i>e</i> to <i>f</i>	17·845
Difference	18·842=18 6 30	M. F. P.	4·393=4 4 $\frac{1}{2}$

Hence it appears, that to plow field A from *g* to *h*, the man, &c. must travel 18M. 6F. 30P. farther than it would be requisite for them to travel to plow the same field in furrows of a similar width from *e* to *f*; and the manual labour alone would amount to four shillings and four pence three farthings more.

It also appears, that it would be necessary to have two prices for executing the different operations in each field; which, though the most correct plan, would be attended with more trouble than most people would be inclined to bestow. Another method, more simple and perhaps sufficiently accurate for practical purposes, is, by finding the mean length of furrow that the arable fields on a farm will admit; and to apportion the price of each operation by the mean length found,

It would sometimes be in favour of the labourer, and at other times against him, but, in the long-run, nearly equal.

EXPLANATION OF TABLE III.

TABLE III. shews the square root (or mean length of the sides) of fields containing from one quarter to forty acres. From which double the mean width of the headlands being deducted, will give the mean length of furrow.

EXAMPLE.

Field A is 6.65; say 6.50: by referring to the Table, the square root, or mean length of the side, is 8 chains 06 links: deduct 1 chain (double the width of the headland), and the remainder will be 7 chains, the mean length of furrow in field A.

To find the mean length of furrow of several fields. Add the contents together, divide the total number of acres by the number of fields; and the quotient will be the average number of acres: which compare with the Table for the square root. Deduct double the mean width of the headland from the square root, and the re-

mainder will be the mean length of furrow in the fields.

EXAMPLE.

Fields.	Contents in acres.
A	6·65
B	16·00
C	21·50
D	34·00
E	17·43
F	5·19
G	19·26
	<hr/>
7	120·03
	17

By Table III. the square root of 17· chains. links.
acres is : 13·04

Deduct double the supposed mean width of headland 1:04

The mean length of furrow in fields A,
B, C, D, E, F, G 12.

The mean length of furrow being found; the number of miles that each implement requires to be moved, to work an acre, may be found in the column under the length of the furrow in Table I.: and in the column under the mean length of furrow in Table II. will be found the expense, at one shilling *per* day, of the manual labour of

working an acre with implements of different widths : which sum being multiplied by the usual pay of a labourer, as before described, will shew the value of the manual labour of performing the different operations.

Yearly servants might be paid weekly for the extra work performed by them.

The advantages arising from this plan, were it generally adopted, would be, that each man might execute an additional quantity of work, and thus be enabled to support his family without parochial aid ;—a spirit of industry would be disseminated throughout the great body of provincial poor,—highly beneficial to the community at large; and the benefits, hence more immediately derivable by the farmer, would be the consequent depression of the poor-rates,—and the saving in many agricultural operations, in the proportion, that the expence a man and the number of horses used with each implement bear, to the expence of a man alone.

EXPLANATION OF TABLE IV.

For Manuring Land.

Most occupiers of land know, after manuring a field, how many loads they laid upon it : but few

take the trouble previously to calculate the proper distance to lay the heaps apart, so as to have a given number of loads applied to each acre.

The late Rev. H. Close, Rector of Hordle, Hants, calculated a table for this purpose: but it applied merely to those cases where the rows of manure and the heaps in the rows were equidistant; which will seldom occur when manuring arable land, as the distances of the rows will in most instances depend upon the width of the lands. A table for the same purpose was also published by Mr. J. Cullyer, of Wicklewood, in the county of Norfolk. Both these tables are useful as far as they go, but appear to have been calculated more with a view to ascertain the number of loads *per* acre after the manure has been laid on, than to direct the husbandman at what distances to lay the heaps, and how many to make of a load, in order to have a given number of loads applied to each acre.

Table IV. is calculated to shew the necessary particulars at sight.

EXAMPLE.

Suppose the lands to be 10 yards wide, or that the rows of manure are required to be 10 yards apart; and that it is proposed to lay 17 loads

upon an acre: find 10 in the first column, then look down the fourth column for 17; and parallel to 17·2 in the second and third columns, will be found $5\frac{1}{2}$, 5; implying that the heaps in the rows must be $5\frac{1}{2}$ yards apart, and each load made into 5 heaps.

Again.—If the rows be required to be 9 yards apart, and 15 loads to be laid upon an acre: find 9 in the first column, and, on casting the eye down the fourth column, it will be found that it may be done in two ways: (the farmer may adopt which best suits his convenience:) that is to say, by laying the heaps in rows 7 yards apart, and making 5 heaps of each load; or by making each load into 7 heaps, and laying the heaps 5 yards apart.

Filling, emptying, and spreading manure, will be most expeditiously done by the cubic yard.

It may not be amiss here to notice a very simple contrivance, adopted by many farmers who aim at regularity in the distribution of their manure. It is a light chain, about nine or ten yards long; having a wooden clog fastened to one end, and a ring at the other end, large enough to be easily hung on a hook driven into the axle-tree close to the near wheel of each cart: there is also a ring instead of a link at the distance of every half-yard from the end-one to the middle of the chain, to admit

of its being attached to the cart at any required length. When hung on at the length, the heaps of manure are intended to be laid apart; a heap is dropped; the horses are then suffered to move on till the clog is drawn opposite to the heap; they are then stopped, and another heap dropped; they are afterwards moved on till the clog is drawn opposite to the last heap: and in this manner they proceed till the field is finished; observing always to unship the chain from the empty cart, and to hang it on the full cart.

EXPLANATION OF TABLE V.

Shewing the Expence of making new Ditches of various Dimensions, according to the Tenacity of the Soil.

In every district, custom seems to have established a certain width and depth for a ditch; the price of which is pretty generally known throughout that district. But should a person wish to make a ditch, varying in any particular from the customary dimensions of those in the neighbourhood, he would find a difficulty in ascertaining the price of making one.

This Table is calculated on the statute pole of $5\frac{1}{2}$ yards or $16\frac{1}{2}$ feet, and also upon the supposition that the farmer is aware of the value of digging a cubic yard of the soil where the ditch is to be made.

EXAMPLE.

What should be given *per* pole for making a ditch 5 feet wide at top, 2 feet wide at bottom, and 4 feet deep; where the value of digging a cubic yard is 3*d.*?

On a line with 5 feet in the first column, 3 feet in the second, and 4 feet in the third, and under 3*d.* *per* cubic yard, will be found $2 \cdot 450 = 2s. 5\frac{1}{2}d.$: the answer.

But should the person wishing to make the ditch, be ignorant of the value of digging a cubic yard of the soil; this Table will, notwithstanding, enable him to ascertain the expence of making the intended ditch. His plan will be to procure the dimensions of the ditch usually made in the country where he resides; and also the price; then, by comparing those dimensions with the Table, and having found similar dimensions, by looking through the columns to the right, he will probably find the price given for digging a pole. The column in which he may find the price, will assist him also in finding the value of digging a ditch of any other dimensions.

EXAMPLE.

A person wishes to find the expence *per pole* of making a ditch 6 feet wide at top, 2 feet wide at bottom, and 5 feet deep;—having no other criterion to judge from, than the ditches of the country for which, on soils similar to that where he wishes to make the new ditch 1*s.* 10*d.* = 1.833, is given for a ditch 4 feet wide at top, 2 feet wide at bottom, and 3 feet deep.—Find 4, 2, and 3, in the Table; then direct the eye along the same line of figures; and 1.833 corresponding to 1*s.* 10*d.* will be found under 4*d.* *per cubic yard*: and in the same column (under 4*d.* *per cubic yard*) on a line with 6, 2, 5, (the dimensions of the intended new ditch,) will be found 4.062, corresponding to 4*s.* 0 $\frac{3}{4}$ *d.* which is the value of digging a pole of the required ditch. Or it may be found as follows: By Table V. the usual ditch of the country, 4, 2, 3, for which 1.833 *per pole* is given, requires 5.5 cubic yards of soil to be moved, (*see the second column;*) and the intended ditch 6, 2, 5, requires 12.2 cubic yards of soil to be moved: then,

$$\text{As } 5.5 : 1.833 :: 12.2 : 4.066 = 4 \text{ } 0\frac{3}{4}.$$

Directions for ascertaining the Amount due for Rent, Wages, or Work, at any Sum per Annum, or per Acre.

To find the amount of money due for wages or rent, multiply the decimal corresponding with the number of weeks and days (*see Table X.*) by the sum *per annum*; and the product will be the answer.

EXAMPLE.

What sum is due for 37 weeks and 4 days wages at 20*l.* *per annum*?

By Table X. $\frac{37}{Wks. Days}$ 4 is equal to .723 part of a year multiplied by the an. sum of 20 produces $\frac{14.460}{14.460 = 14l. 9s. 2\frac{1}{2}d.}$ the answer.
(*See Table IX.*)

EXAMPLE.

What sum is due for 29 weeks rent at 80 guineas *per annum*?

By Table X. 29 weeks = .558

$$80 \text{ guineas} = 84l. \quad 84$$

$$\underline{2232}$$

$$4464$$

produces $\frac{46.872}{46.872 = 46l. 17s. 5\frac{1}{4}d.}$ the answer.

EXAMPLE.

What sum is due for 1 year and 32 weeks rent at 340*l. per annum*?

$$\begin{array}{r} 1 \text{ year } 32 \text{ weeks} = 1\cdot615 \\ \text{Annual rent} \quad \quad \quad 340 \\ \hline 64600 \\ 4845 \\ \hline \end{array}$$

the answer.
 $549\cdot100 = 549l. 2s. 0d.$

The money due *per acre* may be found by Tables VII. and VIII. if the product be required in shillings, &c.; and by Tables VII. and IX. when the products are required in pounds.

EXAMPLE.

How much is due for hoeing 3*r.* 27*p.* of turnips at 7*s. per acre*?

By Table VII. $\frac{R.}{3} \frac{P.}{27} = .318$ parts of an acre multiplied by $\frac{7}{\hline} \frac{s.}{d.}$ the answer. produces $6\cdot426 = 6\ 5$

(See Table VIII.)

EXAMPLE.

How much is due for reaping 23*a.* 2*r.* 13*p.* of wheat, at 14*s. 9d. per acre*?

By Table VII. $\frac{A.}{23} \frac{R.}{2} \frac{P.}{13} = 23\cdot29$
By Table IX. $14s.\ 9d. = .737$

$$\begin{array}{r} 16303 \\ 6987 \\ \hline 16303 \\ \hline \end{array}$$

the answer.
 $17\cdot16472 = 17l. 3s. 3\frac{1}{2}d.$

EXPLANATION OF TABLES XV. XVI. XVII. and XVIII.

*Shewing the dead profitable Weight of Neat Cattle,
Calves, Sheep, and Swine.*

IT has frequently been remarked, that those who are the most skilful, in general manage their concerns with the least trouble. A person having an article to dispose of, would be more likely to meet with a purchaser by offering it at a fair market-price. To ask wide of the value, either betrays ignorance of the subject, or an opinion that the intended purchaser is unacquainted with his business. And on the other hand, if a fair price be demanded for goods, and the person desiring to purchase bids considerably under the value for them, he manifests either a want of knowledge, or thinks contemptibly of the judgment of the seller.

These observations are not inapplicable to many cases that occur in disposing of the produce of the soil.

In selling corn or hay, the measure or weight is usually known: and the only question to be determined is the market-price; which will of course

vary according to the quality. But in dealing for fat cattle, the weight is separately computed by each party, and the price per stone calculated according to their respective computations of the weight and estimation of the quality : which frequently occasions a material difference in the estimated value, particularly where one or both of the parties happen to be inexperienced.

Nothing but continual practice will enable any one to guess the weight of animals with accuracy. If the attention of a person, deemed expert in this art, have been for a length of time diverted from it to other objects, he will not, on resuming the subject, immediately feel that confidence in his own opinion that he used to do when in the exercise of it. It must necessarily follow, that those who have only occasionally a few fat animals to dispose of, with no other opportunity of acquiring information than from their own concerns, will meet a purchaser upon very unequal terms ; it being the principal study of the latter, who have the additional advantage of weighing the animals when dead : the only sure criterion to form a correct judgment upon.

If a person unacquainted with the value of an article he may wish to dispose of, should ask about the real value for it, this must be purely acci-

dental: for he would be as likely to demand considerably above or below: but in valuing fat animals, several causes might combine to induce him to put too high a price upon them.

To remedy these inconveniences, a set of tables was calculated by Mr. Fenton, of Northumberland, for ascertaining the dead weight of the four quarters, by measuring the animal while alive: and if it be moderately fat, of perfect symmetry, and carry its weight regularly throughout, these tables may afford a tolerably accurate idea of the truth: but when an animal varies in any degree from these essential qualities, they must inevitably err. The tables are calculated upon the supposition that the animals are perfectly cylindrical; and each cubic foot is supposed to weigh 42lb.: "the girth is taken just behind the shoulder-blade; and the length, from the fore-part of the shoulder-blade, to the bone in the tail that plumbs the line with the hind-part of the buttock." The dimensions may be worked by the rule for finding the contents of a cylinder by the circumference; that is, by squaring the girth, multiplying the product by .07958 for the area of unity, or (which will be near enough for the present purpose) by .08 and multiplying the last product by the length for the solid contents.

EXAMPLE.

Suppose an animal measured, according to the foregoing directions, girth 6 feet 9 inches, length 5 feet: what will be the weight of the quarters when dead, in stones of 14 lb. supposing each solid or cubic foot to weigh 42lb.=3 stones?

By Table VIII. the decimal part of a foot corresponding to 9 inches is .75: therefore the girth 6.75

$$\begin{array}{r}
 \text{multiplied by} \quad 6.75 \\
 \hline
 3375 \\
 4725 \\
 4050 \\
 \hline
 \end{array}$$

produces 45.5625 the square
multiplied by .08

produces 36.45 the area of the circle
multiplied by .5 the length

gives 18.225 the contents in cub. feet
multiplied by 3. the No. of stones in 42lb.

produces 54.675 = 54 stones lb. 9 the answer.

When animals are heavy before (where the girth is taken), and light in the hind-quarters, they will measure so as to appear to weigh more than they will turn out; and if light before and heavy behind, they will not measure, by the ostensible

weight, so much as they will actually be found to do.

In order to ascertain the real weight with greater precision, and thereby enable a seller to meet a purchaser upon equitable terms, Tables are subjoined, shewing the proportion that the carcase or quarters of an animal dead, bears to the gross live weight: the accuracy of which has been ascertained by experiments made upon almost every breed of cattle, sheep, &c. this country produces, and of various degrees of condition.

In each of the Tables are separate columns for the different state of fatness, *viz.* for those only just marketable,—for fat, and extra fat, or such as have arrived at a perfect state of ripeness.

Taking an ox alive as 1, the proportionate weight of the carcase or quarters will vary from .6 to .7; that is to say, the carcase of an ox merely marketable, will weigh about 6-tenths of the whole; the quarters of a fat ox will be .65 or 6-tenths, and 500 parts of the gross weight; and the carcase of a perfectly ripe ox will be 7-tenths of the live weight.—Consequently, the offal of a marketable ox will be .4, of a fat ox .35, and of a ripe ox .3.

The component parts of a ripe ox (fasted) have been found to correspond nearly to the following proportions:

Cold	Carcase or quarters, skirts and kidneys: meat ·6, bone ·1	·7000
	Loose fat	·0900
	Hide and horns	·0550
	Head, brains, and tongue.....	·0230
	Feet	·0140
	Heart, lights, sweetbread, and bladder	·0084
	Tripe (without fat) feck, reed, liver, gall, and melt	·0256
	Entrails and contents	·0362
	Blood	·0278
	Heat given out	·0200
		<hr/>
		1·0000

So if the live weight of a ripe ox (fasted) be multiplied by the proportional number opposite to either of the respective parts, the product will be the weight of that component part.

EXAMPLE.

If 200 stone, the supposed weight of a ripe ox alive, be multiplied by ·7, it will produce 140

stones, which is the weight of the carcase; 120 stones of meat, and 20 stones of bone;

that is, $200 \times .6 = 120$ of meat

$200 \times .1 = 20$ bone

$200 \times .7 = 240$ the carcase.

The carcase of an ox merely marketable, bears a proportion of .6 to the gross live weight; about .5 of which is meat, and .1 bone.

To find the dead profitable weight of NEAT CATTLE by Table XV. it will be necessary to ascertain the live weight; which being done, and the weight found in the first column, look to the right, and in the second, third, or fourth columns, (according to the condition of the animal) will be found the weight of the quarters.

EXAMPLE.

If an ox, alive, fasted about the usual time, weigh 14cwt. 1qr. 4lb. the proportional weight of the carcase, if barely marketable, will be 120 stone; if fat, 130 stone; if ripe, 140 stone; and if more than moderately fat, but not quite ripe, the mean between the two; namely, 135 stones, &c. &c.

The proportional weight of hide and tallow is given in the fifth column : and it will in most cases be found, if the carcase exceed the weight found by the Tables, (according to the degree of fatness of the animal as before explained), that there will be a deficiency in the weight of the hide and tallow ; and when the carcase does not weigh so much, it may safely be concluded that there is an excess of hide and tallow. This may arise from different causes ; but, perhaps, nothing contributes to produce this variation more than the age of the animal: young animals seldom having so large a proportion of loose fat as those which are older ; or, to speak technically, “ they never die so well.”

It will however occur to the reader, that the Tables will, in either case, shew the dead profitable weight—allowing the buyer a fair proportion of offal.

If the gross weight of a SHEEP (fasted) be expressed by 1, the proportion that the carcase bears to the whole, will vary from .58 to .68.

To find the dead profitable weight of sheep by Table XVI. it will be necessary to deduct the esti-

mated weight of the wool, and any extraneous matter adhering thereto, from the gross weight ; and seek in the Table for the remainder only.

EXAMPLE.

Suppose a sheep moderately fat weighs 1 cwt. 2qrs. 0lb. and the wool, &c. is estimated at 6lb. ; deduct 6lb. from 1 cwt. 2qrs. 0lb. and refer to the Table for the remainder; namely, 1 cwt. 1 qr. 22lb. and parallel to it, in the third column, will be found 12 stone 7-10ths. = 12 stone 6lb. the weight of the carcase or quarters.

The proportion that the sides, head, feet, and flae of SWINE, bear to the gross weight if expressed by 1, varies from .75 to .85 ; and the method of finding the dead weight by Table XVII. is similar to that before explained for ascertaining the dead profitable weight of cattle and sheep.

If the gross weight of a CALF be expressed by 1, the proportional weight of the carcase will be found to vary from .56 to .64.

The live weight of CALVES should be taken about noon, previous to their being suckled ; and the weight of the carcase may be found by Table XVIII.

according to the directions given above, for ascertaining the weight of other animals.

The live weights are to be taken in hundred-weights, quarters, and pounds;—and the proportional dead weights are given in London stones of 8lb. and tenths of stones. But in order to render these Tables more generally useful, Table XIX. (for the equalization of weights) is annexed, from a tenth, to 300 London stones of 8lb.;—shewing the corresponding number of stones of 14lb. scores of 20lb. stones trone weight—(consisting of 16lb., each pound being 20 ounces Amsterdam weight, equal to 21lb. 7-tenths avoirdupoise weight)—and also the proportional number of hundred-weights, quarters, and pounds.

EXPLANATION OF THE TABLES OF WEIGHTS AND MEASURES.

THE variety of weights and measures is a source of perplexity to agriculturists in general, and particularly to those whose inclination may induce them to quit their native place to pursue the profession of a farmer in a distant part of the kingdom. They need no other obstacles than what nature presents, to deter them from embark-

ing their capitals in distant concerns: the difference of soil and climate, however, are not the only obstacles they have to contend with;—they have innumerable difficulties to surmount, of which those who never ventured beyond the limits of their native county can have only a faint idea.

The jealous reception which fresh faces sometimes meet with from native inhabitants, and the unwillingness of the latter, in many instances, to afford that kind of information which every person in civilized society has a right to expect from another, tends materially to increase the difficulties of the stranger. In order to diminish those difficulties, and render the inhabitants of different districts more intelligible to each other, Tables of Scotch and English Weights and Measures are subjoined; and also a Table for making MEASURES *equal in capacity to the STANDARD WINCHESTER BUSHEL*, but of various depths and diameters.

ENGLISH WEIGHTS.

TROY, the original weight of the realm, is now used chiefly in weighing gold, silver, and precious stones; and for ascertaining the strength of spirituous liquors.

Apothecaries weight is merely a different subdivision of the pound troy: this weight is only used in compounding medicines.

Avoirdupoise weight was first used in the reign of Henry the Eighth.—By this weight are weighed all kinds of flesh, corn, hay, straw, bread, wool, cheese, butter, hemp, flax, tallow, pitch, tar, wax, and all metals, except gold and silver; grocery, drugs, and all commodities which are garbled, and upon which any refuse is made.

SCOTCH WEIGHTS.

HAY, wool, Scotch lint, hemp, butter, cheese, tallow, &c. are always sold in Scotland by trone weight.

A London-load of hay (that is, 18cwt.) makes of trone weight, nearly 93 stones, (reckoning 20lb. Amsterdam weight to the stone.) Therefore,

	s. d.	£. s. d.
Hay at 0 5 per st.	=	1 18 9}
0 6	2 6 6	
0 7	2 14 3	
0 8	3 2 0	per load.

<i>s.</i>	<i>d.</i>	<i>£.</i>	<i>s.</i>	<i>d.</i>
Hay at 0	9 per st.	=	3	9 9
0 10		3	17	6
0 11		4	5	3
1 0		4	13	0
1 6		6	19	6
2 0		9	6	0
2 6		11	12	0

per load.

ENGLISH MEASURES.

THE origin of long or lineal measure was taken from a grain of barley: of which three selected out of the middle of the ear, and well dried, make one inch. But the legal standard to which all are now referred, is preserved in the Exchequer.

Square measure is used to estimate all kinds of superficies; such as land, paving, plastering, roofing, tiling, thatching, and every thing that has length and breadth.

By cubic or solid measure, are found the contents or capacities of all bodies having length, breadth, and depth.

Measures of capacity have been explained by several statutes:

By an Act passed in the 13th and 14th of King William the Third, chap. 5. sect. 28, every round bushel with a plain bottom, being made $18\frac{1}{2}$ inches throughout, and 8 inches deep, is to be esteemed a legal Winchester bushel, according to the standard in the Exchequer.

By Magna Charta, 9th Henry Third, chap. 25, one measure of corn shall be used throughout the realm; viz. the legal Winchester bushel *only*.

By 15th Richard Second, chap. 4th, none shall buy corn but by the Winchester bushel, upon forfeiture of the corn so bought.

By 22d Charles Second, chap. 8, none shall sell corn by any other than the Winchester bushel, under penalty of forty shillings to the poor.

If any mayor, or constable, shall suffer any other measure to be used, (or if upon complaint of this statute, they shall not endeavour to punish the same), they shall forfeit five pounds; one moiety to the informer, the other to the poor.

By 22d and 23d Charles Second, chap. 12, every person who shall buy or sell corn by any other measure, shall forfeit (besides the penalty of the former act), all corn bought or sold contrary to this Act, to the person informing.—Upon a complaint being made to any magistrate, it will rest with the defendant to prove that he has not sold by any other than the legal standard.

By 1st of Queen Anne, statute 1, chap. 1, the bushel water-measure, for fruit, is to be round, and in diameter $18\frac{1}{2}$ inches within the hoop, and 8 inches deep; and so in proportion for any greater or lesser measure, and is to be heaped as usual.

By 12th of Queen Anne, statute 2, chap. 27, the coal-bushel is to be round, with a plain and even bottom, and to be *nineteen inches and a half* from *outside to outside*, and to contain *one Winchester bushel* and *one quart of water*, according to the standard of the Winchester bushel.

It hence appears, that three different sorts of bushels are now used as standard measures; viz. the Winchester bushel for corn and grain, which

is to be stricken (with a round strike); the bushel water-measure for fruit, which is to be heaped; and the coal-bushel, which is also to be heaped.

Corn-bushels, made according to the dimensions of the standard, viz. $18\frac{1}{2}$ inches diameter, and 8 inches deep, have been considered inconvenient for general purposes; being too wide for the sacks commonly used by farmers. Narrower, and deeper measures have therefore been substituted, and adopted by most persons in the corn-trade.

The innumerable errors that are committed, in attempting to make measures of different dimensions, but to contain the same quantity of corn as the legal Winchester bushel, has produced much unpleasant controversy; and the feelings of many persons have suffered, more frequently through a want of information on the subject, than from being influenced by motives to which errors of this description are generally attributed.

For instance. Suppose a measure differing in dimensions, but containing the exact number of cubical inches as the legal standard bushel, be taken to the Exchequer, Guildhall, or any other

place where a standard is preserved, the officer attending would not hesitate to stamp it as a legal bushel : and the person to whom it might belong, would feel confident of its being a just measure.— Yet the contrary is demonstrable ; for though its cubical contents be equal to, it would not contain the same quantity of corn as the standard. This may at first appear paradoxical ; but will easily be comprehended, if it be considered that in striking off the superfluous corn, a pressure is produced, which occasions a greater quantity to be contained within the limits of the bushel, than would otherwise happen, if the corn above the edge of the measure were taken off while in its light state : and the effect of the pressure being more immediately felt near the surface, it will be obvious, that any deviation from the specific diameter, will produce a corresponding difference in the quantity that will be contained within the measure.

The pressure in striking, causes an increase of corn nearly equal to the cubical contents of three sixteenths of an inch in depth, upon the surface exposed.

The surface of the legal bushel $18\frac{1}{2}$ inches diameter, is 268·8 superficial inches, multiplied by ·1875, (the decimal corresponding to three six-

teenths of an inch) will produce 50·4 cubic inches ;—the increase of corn occasioned by the pressure in striking : but a measure 14 inches diameter, exposes a surface of only 153·9 superficial inches, multiplied by $1875 = 28\cdot8$ cubic inches, the increase occasioned by pressure in striking.

	In.	Cub. In.
Increase by striking a measure $18\frac{1}{2}$ diameter		50·4
Increase by striking a measure 14 diameter		28·8
Difference		21·6

Hence it follows, that it will be necessary to increase the depth of the latter measure, in order that it may *exceed* the contents of the Winchester bushel by 21·6 cubic inches :—which would then contain an equal quantity of corn with the standard measure, allowing for the increase occasioned by the pressure in striking.

EXAMPLE.

What ought to be the depth of a measure $13\frac{1}{4}$ inches diameter, in order that it might contain the same quantity of corn as the legal bushel : supposing that the pressure in striking produces an increase equal to the cubical contents of

three sixteenths of an inch, on the surface exposed?

By Table XX. the contents of a measure $13\frac{1}{4}$ inches diameter, (see the first column) and 15 inches $\frac{5}{8}$ -eighths deep, (see second column) exceeds the contents of the standard bushel by 2 \cdot cubic inches, (see third column). But the area of a circle $13\frac{1}{4}$ inches diameter, being only 137 \cdot 8 superficial inches,—the increase occasioned by the pressure in striking, will only amount to 25 \cdot 8, (see fourth column), being 24 \cdot 6 cubic inches less than the increase by striking the standard.—To make up this deficiency, it will be necessary to add as much to the depth of the measure, $13\frac{1}{4}$ inches diameter, as will make its contents exceed the contents of the Winchester bushel, by 24 \cdot 6 cubic inches: which may be done as follows.—In the fifth column it will be found, that every eighth of an inch in depth, of a measure $13\frac{1}{4}$ inches diameter, contains 17 \cdot 22 cubic inches; therefore, if 3-sixteenths of an inch be added to the depth, it will then contain nearly the same quantity of corn as the standard.

Cubical contents of the Winchester

bushel	2150 \cdot 4
Increase by striking	50 \cdot 4
	<u>2200\cdot8</u>

Brought over	^{Cub. In.} 2200.8
Cubical contents of Measure 13 $\frac{1}{4}$	
inches diameter, and 15 inches	
5-eighths deep (2 cubic inches	
more than the legal standard)... 2152.4	
Increase by striking 25.8	
Add to the depth $\frac{3}{16}$ of an inch	
$\left\{ \begin{array}{l} \frac{1}{8} \dots\dots 17.21 \\ \frac{1}{16} \dots\dots 8.6 \end{array} \right\} \dots\dots\dots\dots\dots\dots$	25.8
	<u> </u> 2204.0 <u> </u>
Difference... 3.2	

Thus it will be necessary to make the latter measure 15 inches 13-sixteenths deep, instead of 15 inches 5-eighths, which would then contain 3 $\frac{1}{2}$ cubic inches more corn than the standard bushel. It will, in most cases, be difficult to make measures, varying in dimensions, to correspond precisely with the contents of the standard: the best plan, however, in all such cases, will be to err on the safe side.

The liability to error by deviating from the precise dimensions, as established by law, in making corn measures, it is presumed has been sufficiently elucidated: and it will require but little attention to perceive, that a strict adherence to the legal dimensions, in the construction of fruit and coal measures, is indispensable: for it will be obvious

to every person, that a larger heap will lay upon the area of a circle $19\frac{1}{4}$ inches diameter, than will lay upon a circle of any lesser diameter. To prevent any excuse respecting the inconvenience of these measures, the dimensions of the coal-sacks have been particularly described.

By 3d of King George the Second, chap. 26, sect. 11, coal-sacks are to be full 4 feet 2 inches in length, and 26 inches in breadth after they are made: and dealers in coals are to use no others.

It was further enacted, That no sacks used for the carriage of coals are to be less than four feet in length, and full two feet in breadth within side the sack.

Sixty solid or cubic feet of Newcastle coal make one London chaldron; a cubic foot of ditto generally weighs 50lb. avoirdupoise; a heaped bushel thereof weighs 83lb. avoirdupoise; and 36 bushels (or 1 chaldron) weigh 26.67 hundred-weight; that is, 2988lb. avoirdupoise.

It would be productive of much good to the community, were corn of all kinds, as well as coal, &c. to be sold by weight instead of measure.

By 5th of Queen Anne, chap. 27, any round vessel, commonly called a cylinder, having an even bottom and being *seven inches* diameter throughout, and six inches deep from the top of the inside to the bottom, or any vessel containing 231 cubical inches and no more, is to be deemed a lawful wine-gallon; and 252 of such gallons shall be deemed a tun of wine: 126 a butt or pipe; and 63 a hogshead of wine.

Beer-measure for London is 36 gallons to the barrel. Ale-measure for ditto is 32 gallons to the barrel; beer and ale for the country is a mean between the two, being 34 gallons to the barrel.

Every city, borough, or market-town, is to have one of every weight and measure, of brass or other metal, according to the standard in the Exchequer; there to remain in the keeping of the mayor, bailiff, or other head-officer of such city, borough, or market-town, as the king's standard; and the inhabitants are to cause common weights and measures to be made according to the said standard weights and measures of such city, borough, or market-town: which are to be examined and marked by such mayor, bailiff, or other officer, in whose possession such standard shall

remain: and no inhabitant is to sell, buy, keep, or make use of, any other weight or measure whatever, than according to such standards.

SCOTCH MEASURES.

THE Stirling jug (containing one Scotch pint) is the original standard of all liquid and dry measures, and of all weights, in Scotland: it contains 103.404 cubic inches:—when filled with the water of Leith (with the greatest accuracy) the water weighed 3lb. 7oz. of Scots troy, or Amsterdam weight.

By the Act of Union, the barrel for English country-measure of 34 gallons, making	Cub. In. 9588
Is reckoned equal to 12 Scots gallons;	
making.....	9626.7

Difference... 338.7

<i>Scotch gallons.</i>	<i>English gallons.</i>	
	Beer.	Wine.
16 ... = ... 46.935	... = ...	57.3
18.4 ... = ... 54	... = ...	65.922
17.6 ... = ... 51.6	... = ...	63

Amsterdam and Trone, being the weights commonly used in Scotland, have been inserted here, and the local weights omitted; because it was considered, that the variety would tend rather to perplex than afford any useful information.

Were an universal standard of weights and measures to be established, it would greatly facilitate the transacting of every description of business: but this unfortunately, at present, appears an object more to be desired than likely to be speedily accomplished.

TABLE II.—(See page 9.)

For ascertaining the Expence, (in Shillings and Decimal Parts of a Shilling,) of the manual Labour attending Plowing, Harrowing, Rolling, or otherwise working an Acre, with Implements of different Widths, in Fields of various Sizes.

For the Pence corresponding to the Decimal Parts of a Shilling see Table VIII.

TABLE XI.

Show ing the Decimal corresponding to every Pound in the Stone of 8 lb.

Pounds.	Decimals.	Pounds.	Decimals.
1	.125	5	.625
2	.250	6	.750
3	.375	7	.875
4	.500	8	1.000

TABLE XII.

Show ing the Decimal corresponding to every Pound in the Stone of 14 lb.

lbs.	Dec.	lbs.	Dec.	lbs.	Dec.
1	.074	6	.429	11	.786
2	.143	7	.500	12	.887
3	.214	8	.574	13	.929
4	.286	9	.643	14	1.000
5	.357	10	.714		

TABLE XIII.

Shewing the Decimal corresponding to every Pound in the Score, or 20 lb.

lbs.	Dec.	lbs.	Dec.	lbs.	Dec.
1	.050	8	.400	15	.750
2	.100	9	.450	16	.800
3	.150	10	.500	17	.850
4	.200	11	.550	18	.900
5	.250	12	.600	19	.950
6	.300	13	.650	20	1.000
7	.350	14	.700		

TABLE XIV.

Shewing the Decimal corresponding to every Pound in the Stone, Trone Weight, consisting of 16 lb. each Pound being 20 oz. Amsterdam.

lbs.	Dec.	lbs.	Dec.	lbs.	Dec.	lbs.	Dec.
1	.062	5	.312	9	.562	13	.812
2	.125	6	.375	10	.625	14	.875
3	.189	7	.437	11	.689	15	.937
4	.250	8	.500	12	.750	16	1.000

TABLE XV.—(See page 31.)

Shewing the Dead Profitable Weight of Neat Cattle.

When Oxen are weighed alive, without being fasted, deduct 10 Stones from the Dead Weight found by this Table.

Live weight fasted. cwt. qrs. lbs.	Dead Weight.			
	Carcase, marketable.	Carcase, fat.	Carcase, extra fat.	Hide and Tallow. st. 10ths.
